## Linear Referencing – The Old

The concept of referencing things by the measure along a path has been around for centuries

- From very old Japanese examples
  - 300+ years old
  - 100m long scroll
- To the mid-20<sup>th</sup> century used by Vicroads
  - Major state highway scrolls used for the location of assets

## Linear Referencing – The Old, Current

The Stars on this road represent locations along the network

- The route is calibrated by the field driven length.

The problem is that the spatial representation of the route does align with what is on the ground.

# An Absolute Location Reference versus A Relative Location Reference

## Absolute Reference (aka GPS, Coordinates)

- Is independent of any graphical representation

## Linear referencing (aka Chainage, SRRS)

- Location is relational to the location definition of another GIS geometry

**Dynamic Segmentation**  
Location by route measure

ROUTE	ID	START MEASURE	START MEASURE	FEATURES DESCRIPTION	GEOMETRY
2000F	A	50		Vehicle Breakdown	Point
2000F	B	150	200	60 Kph Zone	Line
2000F	C	70	240	Wire Rope Barrier	Line

## The New DTP Approach

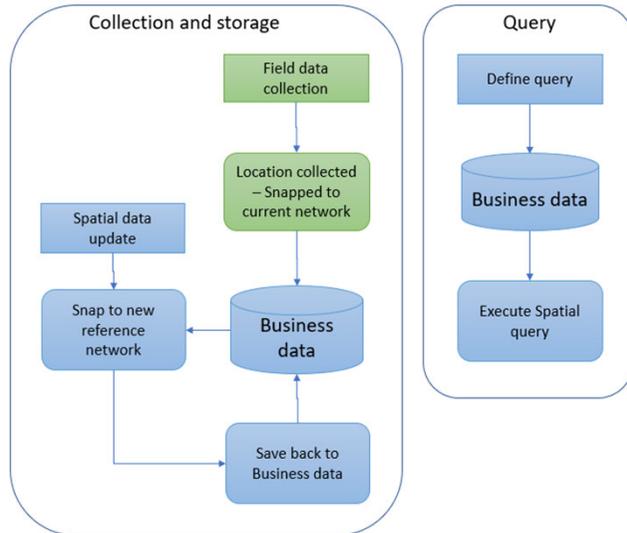

- We have adopted Open Street Map as our operational network geometry for use in a variety of transport applications
  - Implemented a platform that conflates our authoritative road network for gazetted road names
- Stopped the requirement for roads to be driven and the routes to be calibrated
  - The resolution of aerial photography is such that the ability to pick and geographically locate intersections is as good, if not better than can be done by driving the network
- The systems that require a route measure (chainage) it is calculated dynamically and date stamped
  - Route features are stored as coordinates and measures derived.

## How does that help?

- High frequency of network update can be accommodated
- Field attributes collected on one network can be queried on another
  - By time – older version of the network
  - Network collected against – collected by declared road reported by bus route

**Cheaper** – less people required  
**Reality** – Better represents field  
**Reporting** – Allows for historic reporting

### Current Process

#### Assumptions:

- Data is always held on current version of network
- Queries are always against current network

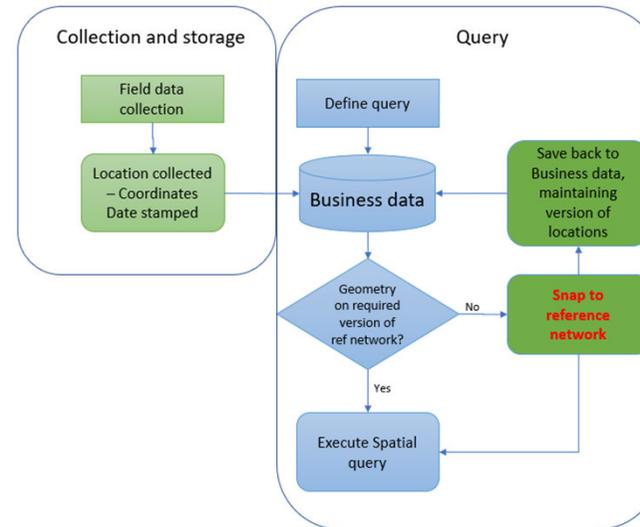

#### Advantages:

- Not pre-processing for queries

#### Disadvantages:

- All data has to be processed with every reference data update
- Queries against "as was" or "to be", networks difficult

### To Be Process

#### Assumptions:

- Data is always held as coordinates and time stamped
- Versions of geometry are maintained

#### Advantages:

- Queries can be made against any epoch of reference network
- Data not held against a road thus more flexible

#### Disadvantages:

- More processing
- More storage required

## The Paradigm Shift

Current	New
Routes created by dissolving on attribute value	Routes generated by geometric path through the network
Routes calibrated by driven route length distance	Routes calibrated by mapped length
Roads layer has all attributes	Roads layer has minimal attributes
Geometry managed along with attributes	Geometry managed independently of the attributes
Manage Attribute in master file	Generate extracts to deliver business value

# The most relevant SDGs related to the presentation and theme of this session

1st relevant SDG

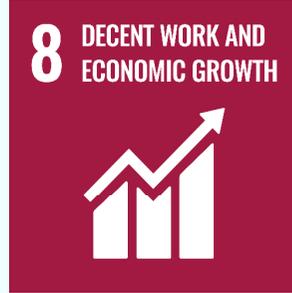

9 INDUSTRY, INNOVATION AND INFRASTRUCTURE

2nd relevant SDG

12 RESPONSIBLE CONSUMPTION AND PRODUCTION

3rd relevant SDG

8 DECENT WORK AND ECONOMIC GROWTH

SUSTAINABLE DEVELOPMENT GOALS

International Federation of Surveyors supports the Sustainable Development Goals
